Private Browsing

- Browsers offer a "private" browsing modes
 - Apple *Private Browsing*, Mozilla *Private Browsing*, Google Chrome *Incognito Mode*, Microsoft *InPrivate* browsing
- What does it do
 - Do not send stored cookies
 - Do not allow servers to set cookies
 - Do not use or save auto-fill information
 - List of downloaded content
 - At the end of a session
 - Discard cached pages
 - Discard browsing & search history
- Does not protect the user from viruses, phishing, or security attacks

2

Is private browsing private?

- It doesn't leave too many breadcrumbs on your device
- It limits the ability of an attacker to use cookies
- But
 - Your system may be logging outbound IP addresses
 - Proxies know what you did ... so do firewalls & routers
 - Your ISP knows who you are and where you went
 - Web servers get your IP address

Answer: *not really*

April 24, 2017

3

Goal

Communicate while preserving privacy

Why?

- Avoid consequences (social, political, legal)
 - E.g., political dissidents
- Avoid geolocation-based services
- Hide corporate activity (who's talking to whom)
- Perform private investigations
- Hide personal info, like searching about diseases you have
- ...

Tor & The Tor Browser

- **Tor** = The Onion Router
- **Tor Browser** = preconfigured web browser that uses Tor
 - Provide anonymous browsing
- Hosted on a collection of relays around the world
 - Run by non-profits, universities, individuals
- 100K to millions of users
 - Exact data unknown – it's anonymous
 - Terabytes of data routed each second

April 24, 2017

CS 419 © 2017 Paul Krzyzanowski

5

History

- **Onion routing** developed in the mid 1990s at the U.S. Naval Research Laboratory to protect U.S. intelligence communications
- Additional work by the Defense Advanced Research Projects Agency (DARPA)
- Patented by the U.S. Navy in 1998
 - Naval Research Laboratory released to code for Tor under a free license
- The Tor Project
 - Founded in 2006 as a non-profit organization with support of the EFF

6

What is anonymity?

- **Unobservability**
 - Inability of an observer to leak participants to actions
- **Unlinkability**
 - Inability to associate an observer with a profile of actions
 - E.g., Alice posts a blog under an assumed name
 - Unlinkability = inability to link Alice to a specific profile

7

Relay

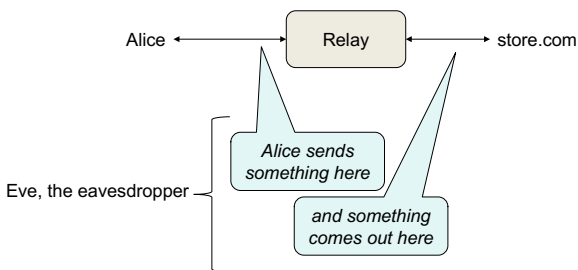

April 24, 2017

CS 419 © 2017 Paul Krzyzanowski

8

Relay

April 24, 2017

CS 419 © 2017 Paul Krzyzanowski

9

Relay with multiple parties

We can use encrypted connections (TLS) to hide network traffic

What if someone eavesdrops on the relay?

April 24, 2017

CS 419 © 2017 Paul Krzyzanowski

10

Multiple relays

You cannot see all activity at one relay

April 24, 2017

CS 419 © 2017 Paul Krzyzanowski

11

Correlation Attack

- If an eavesdropper watches entry & exit of data
 - She can correlate timing & size of data at the 1st relay with outputs of the last relays
 - If Alice sends a 2 KB request to Relay₁ at 19:12:15 and Relay₃ sends a 2 KB request to store-3.com at 19:12:16 and store-3.com sends a 150 KB response to Relay₃ at 19:12:17 and Alice receives a 150 KB response at 19:12:18 ... we're pretty sure Alice is talking to store-3.com

April 24, 2017

CS 419 © 2017 Paul Krzyzanowski

12

Correlation Attack

- You can make a **correlation attack** attack difficult
 - Pad or fragment messages to be the same size
 - Queue up multiple messages, shuffle them, and transmit them at once
- This works in theory but is a pain in practice
 - Extra latency, traffic
 - You still need A LOT of users to ensure anonymity
- Relays should be hosted by third parties to get many different groups as input
 - E.g., a relay within `fbi.gov` tells you all input comes from `fbi.gov`

April 24, 2017

CS 419 © 2017 Paul Krzyzanowski

13

Circuits

- Alice selects a list of relays through which her message will flow
- This path is called a **circuit**
- No node knows if the previous node is the originator or relay
 - Only the final node (**exit node**) knows it is the last node

April 24, 2017

CS 419 © 2017 Paul Krzyzanowski

14

Setting up a circuit (1)

- Alice connects to Relay1
 - Sets up a TLS link to Relay₁
 - Does a one-way authenticated **key exchange** with Relay₁ – agree on a symmetric key, **S₁**
 - Alice picks a circuit ID (e.g., 123) and asks Relay1 to create the circuit

April 24, 2017

CS 419 © 2017 Paul Krzyzanowski

15

Setting up a circuit (2)

- Alice extends the relay to Relay₂
 - Alice sends a message to Relay₁:
 - First part** = "on circuit 1234, send **Relay Extend** to Relay₂ – the message is encrypted with S₁
 - Relay₁ establishes a TLS link to Relay₂ (if it didn't have one)
 - Second part** of the message from Alice: initial handshake with Relay₂, encrypted with Relay₂'s public key
 - Relay₂ picks a random circuit for identifying this data stream to Relay₂, e.g., 456
 - Circuit 123 on Relay₁, connects to Circuit 456 on Relay₂
 - Does a one-way authenticated **key exchange** with Relay₂ – agree on a symmetric key, **S₂**
 - All traffic flows through Relay₁, and is encrypted with S₁

April 24, 2017

CS 419 © 2017 Paul Krzyzanowski

16

Setting up a circuit (3)

- Alice extends the relay to Relay₃
 - Same process – Alice sends a **Relay Extend** message to Relay₂
 - Messages to Relay₂ are encrypted with S₂ and then with S₁

$$E_{S_1}(E_{S_2}(M))$$
 - Relay₁ decrypts the message to identify its circuit (123)
 - Routes message to Relay₂ on circuit 456
 - Circuit 123 is connected to circuit 456

April 24, 2017

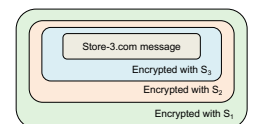

CS 419 © 2017 Paul Krzyzanowski

17

Sending a message (5)

- Alice sends a message to store-3.com
- Each router strips off a layer of encryption
- At the end:
 - Directive to S₃ to open a TCP connection to store-3.com
 - Send messages
 - Get responses

April 24, 2017

CS 419 © 2017 Paul Krzyzanowski

18

Not a VPN

- Neither IP nor TCP packets are transmitted – just data streams
 - Too easy to identify the type of system by looking at TCP formats and responses
- Just take contents of TCP streams and relay the data
- End-to-end TLS works fine
 - TLS sits on top of TCP ... it's just data going back and forth

April 24, 2017

CS 419 © 2017 Paul Krzyzanowski

19

Finding nodes

- Ideally, everyone would use some of the same nodes
 - Otherwise traffic would be distinguishable
- Multiple trusted parties supply node lists
 - Merge lists together
 - **Union**: if popularity-based, danger of someone flooding a list of nodes to capture traffic
 - **Intersection**: someone can block out nodes
 - Multiple parties vote on which nodes are running and behaving well
 - Distributed consensus
- Clients get
 - List of nodes and their public keys

April 24, 2017

CS 419 © 2017 Paul Krzyzanowski

20

Is it anonymous?

- Not really
- You can do a correlation attack
 - ISPs know who's talking to whom
 - May need to access traces from multiple ISPs
 - Can be really difficult if nodes have a lot of traffic (and it's similarly dense)
- Compromised exit node
 - Exit node decrypts the final layer and contacts the service

April 24, 2017

CS 419 © 2017 Paul Krzyzanowski

21

I2P and Garlic Routing

I2P = Invisible Internet Project

- Tor uses "onion routing"
 - Each message from the source is encrypted with one layer for each relay
- Garlic routing
 - Combines multiple messages at a relay
 - All messages, each with its own delivery instructions going to one relay are bundled together
 - Makes traffic analysis more difficult
- Tor **circuits** are bidirectional: responses take the same path
- I2P "**tunnels**" are unidirectional
 - One for outbound and one for inbound: the client builds both
 - Sender gets acknowledgement of successful message delivery

April 24, 2017

CS 419 © 2017 Paul Krzyzanowski

22

Services on top of I2P

- **I2PTunnel**: TCP connectivity
- Chat via **IRC** (Internet Relay Chat)
- File sharing
 - **BitTorrent**
 - **iMule** (anonymous file sharing)
 - **I2PheX**: Gnutella over I2P
- **I2P-Bote**: decentralized, anonymized email
 - Messages signed by the sender's private key
 - Anonymity via I2P and variable-rate delays
 - Destinations are I2P-Bote addresses
- **I2P-Messenger**, **I2P-Talk**
- **Syndie**: Content publishing (blogs, forums)

April 24, 2017

CS 419 © 2017 Paul Krzyzanowski

23

- Tor: far more users → more anonymity
 - Focused on anonymous access to services
- I2P: focuses on anonymous hosting of services
 - Uses a distributed hash table (DHT) for locating information on servers and routing
 - Server addressing
 - Uses cryptographic ID to identify routers and end services
